ABSTRACT

This study aimed to determine prevalence of nasopharyngeal myiasis among camels and evaluate the variation of *Mentha longifolia* oil yield, components, antioxidant activity, and larvicidal effect against *Cephalopina titillator* during three cuts (28^{th} of April, 4^{th} of June, and 22^{nd} of July). Clinical and post-mortem examinations of 300 dromedary camels slaughtered in Giza province, Egypt showed a high prevalence of nasopharyngeal myiasis (58%). Risk factors linked to high infestation were being more than 3 years old (70.8%) and cooler seasons (74%); where it reached 81.3% in Winter. The highest oil yield was obtained on the 22^{nd} of July. The relative percentages of the main constituents (pulegone, followed by eucalyptol, then I-menthone) showed variation in all three cuts. The highest percentage of pulegone (63.79%) was on the 28^{th} of April, followed by 62.41% on the 4^{th} of June, and decreased to 55.25% on the 22^{nd} of July. In contrast, the 3^{rd} cut produced the highest Eucalyptol (18.26%) and I-menthone (9.83%). *M. longifolia* oil at 200mg/mL caused 100% mortality of 2^{nd} and 3^{rd} larvae within 2 and 8h, respectively. Essential oil of the 2^{nd} cut showed superior efficacy compared to ivermectin-treated larvae, with lower LC₅₀ and LC₉₀ values. Light and scanning electron microscopy revealed significant damage to the oil treated larvae, including swelling, degeneration, and atrophy of the cuticle, the mouthparts and antennal lobes. These findings highlighted the danger of nasopharyngeal myiasis, effect of cut dates on *M. longifolia* oil yield and constituents, and its potent anti-*C. titillator*.

Key words: Camel nasopharyngeal myiasis, Cephalopina titillator, Mentha longifolia, Pulegone, Cuts dates.

INTRODUCTION

The one-humped camels (*Camelus dromedarius*) are one of the most essential multipurpose species of livestock in arid and semiarid areas (Faye 2020; Hassan et al. 2024). Through the ages, they are kept for transportation across the desert by Bedouins and for their highly nutritious milk, meat, and hide (Sazmand et al. 2019).

Among the parasitic diseases, camel nasopharyngeal myiasis is deemed a highly prevalent threat that negatively declined health and productivity, causing remarkable economic losses all over the world (Alahmed 2002; Abd El-Rahman 2010; Yao et al. 2022; Hassan et al. 2022). The obligatory camel nasal botfly deposits the first larval instars

of *Cephalopina titillator* (*C. titillator*) in the camels' nostrils (Higgins and Kock 1985). Where the larvae have the ability to invade the nasopharynx and paranasal sinuses and adhere to the mucosa for around a year, which causes extreme discomfort and promote inflammatory changes. So the infested animals are suffered from serious respiratory ailments, such as excessive nasal discharge, snoring, head shaking, as well as inappetence, abortion and decreased milk production (Taylor et al. 2007; Hassan et al. 2022). According to Musa et al. (1989), pneumonia may also result from a subsequent bacterial infection. However, in certain instances, neurological conditions were noted as occurring after the larvae may have gained access to the cerebral cavity (Shakerian et al. 2011).

Prevalence of nasopharyngeal myiasis among Dromedary camels and influence of cuts dates on chemical composition, antioxidant and larvicidal efficacy of *Mentha longifolia* L. essential oil against *Cephalopina titillator*. International Journal of Veterinary Science x(x): xxxx. https://doi.org/10.47278/journal.ijvs/2025.054

There have been numerous reports of the varying prevalence of nasaopharyngeal myiasis around the world, including 91% in Saudi Arabia (Hussein et al. 1982), 58% in Nigeria (Desbordes and Ajogi 1993), 79% in Libya (Abd El-Rahman 2010), 42% in Iraq (Atiyah et al. 2011), 41.67% in Egypt (Khater et al. 2013) and 54.2% in China (Yao et al. 2022).

Traditional treatment of nasal myiasis is mainly relied on macrocyclic lactones (Khater et al. 2013). The widespread of chemotherpeutics might have negative consequences on the food safety and increase of the concerns of establishing drug resistance (Hassan and Ghazy 2022). In light of these challenges, there has been growing interest in alternative control strategies, particularly those are environmentally friendly and sustainable. One promising approach is the use of natural essential oils extracted from plants having larvicidal effects (Abu El Ezz et al. 2018).

Mentha longifolia L. is recognized as a beneficial medicinal plant with various pharmacological and biological activities. The percentage of the main component of M. longifolia essential oils exhibited significant variations worldwide depending on harvest time, geographical location, environmental condition, seasonal variations (Hussain et al. 2008) which affect the regulation of the essential oil biosynthesis (Masotti et al. 2003). Hussain et al. (2010) reported a significant variation in piperitenone and piperitenone oxide contents between summer and winter samples of M. longifolia from Pakistan. Spring and winter samples of *M. longifolia* growing in Tunisia affected the main components of eucalyptol, pulegone, piperitenone, menthone, and isomenthone (Zouari-Bouassida et al. 2018). In addition, Tacer et al. (2018) claimed that carvone is the main compounds in M. longifolia var. Schimperi. Dihydrocarvone (cis and trans isomers) had been detected as the major compound in Croatian (Džamić et al. 2010) and Iranian samples (Nazem et al. 2019).

The essential oil of Mentha longifolia L. is effective in cardiovascular diseases, including improvements in lipid balance, liver and endothelial functions and reductions in blood pressure, oxidative stress and inflammation, promote vascular relaxation, and it has an inhibitory effects on diabetes emergence and angiogenesis (Sut et al. 2021). Yassin et al. (2020) assessed the anticancer efficacy of M. longifolia, and its ability in healing burn wound has been reported by Haikal et al. (2022). Furthermore, the essential oil of *M. longfolia* has antimicrobial activity against *S.* aureus, and E. coli (Jahani et al. 2021). A prominent antifungal effect of M. longfolia extract was observed against Candida strains (Yassin et al. 2020). El-Badry et al. (2010) recorded the anti-parasitic influences of menthol and menthone of *M. longifolia* extract (5-200 µg/mL) on some infectious protozoal diseases e.g. Entamoeba histolytica and Giardia duodenalis. Khani and Asghari (2012) found a anti-insect remarkable features against Tribolium castaneum (a pest of stored products). In the same context, it also showed insect repellent activity, in addition to an inhibitory effect on the growth of insects at the larval and pupal stage (Pascual-Villalobos and Robledo 1998).

Research indicates that *Mentha* oil can significantly reduce the activity and survival of pests like mosquitoes, ants, and cockroaches (Isman 2000; Kumar et al. 2011;

Fouad et al. 2023). A study by Singh and Pandey (2018) found that Mentha oil extract effectively repelled mosquito species, making it a promising natural alternative to synthetic insecticides. Additionally, the oil's effectiveness had been attributed to its ability to disrupt the nervous systems of insects, leading to their mortality (Ben Slimane et al. 2014).

Therefore, the goal of this study is to determine the prevalence of nasapharangyeal myiasis infesting camel, and the associated risk factors along with investigating the variation of the productivity of *M. longifolia* plant, essential oil yield, constituents, antioxidant activity and larvicidal activity as a natural insecticide against *C. titillator* during three cuts dates (28^{th} of April, 4^{th} of June and 22^{nd} of July).

MATERIALS AND METHODS

Animals and parasites

Three hundred Dromedary camels of age 2 to 10 years old were used in this study at Kerdasa abattoir in Giza province. Twenty-five ones were monthly examined along the period extended from February 2024 to January 2025. The camels were clinically examined for the respiratory manifestations before slaughtering. Age and sex of animals were recorded. The head region of slaughtered camels was cut longitudinally through the throat. Then, the nasopharangyl regions, the frontal sinuses and the turbinate bone were investigated for detecting *C. titillator* larvae. The larvae were gathered in sterile labelled plastic cups and transferred to the laboratory.

Cultivation of *M. longifolia* and essential oil study

This experiment was conducted at National Research Center's Agricultural Experimental Station in Nubaria, west of Egypt's Nile Delta (latitude $30^{\circ} 30' 1.4"$ N and longitude $30^{\circ} 19' 10.9"$ E, Egypt). The present study aimed to investigate the variation of the productivity of *Mentha longifolia* plant, essential oil yield, constituents, antioxidant activity and larvicidal activity as a natural insecticide against *C. titillator* during three cuts dates (28th of April, 4th of June and 22nd of July).

Representative soil samples were taken from one layer (0-30cm) before cultivation for physical and chemical analyses according to Jackson (1973). The soil was sandy with 1.03ds.m⁻¹EC and 7.97pH. The cations and anions were measured in meql⁻¹ as follows: 3.8Ca⁺⁺, 0.8Mg⁺⁺, 6.2Na⁺, 0.6K⁺, 0 CO₃⁻⁻, 2.6HCO₃⁻⁻, 5.6Cl⁻ and 3.2So₄⁻⁻.

The seedlings were purchased from Horticulture Research Institute, Agricultural Research Centre, Egypt. Then the seedlings were transplanted in late February into the experimental field with 30cm adjusted to dripper lines, which were 75cm apart. The normal agricultural practices for *Mentha longifolia* plants were done. The plants were irrigated using the drip irrigation system (4Lhour⁻¹).

This study was performed at completely randomized design with three replications. Three cuts were taken on the 28th of April, 4th of June and 22nd of July, respectively. Fresh and dry weights of herb (g plant⁻¹ and ton ha⁻¹) as well as essential oil percentage (%) and yield (mLplant⁻¹ and Lha⁻¹) were recorded.

Essential oil was extracted out by hydro-distillation according to Egyptian Pharmacopoeia (1984), using

Clevenger-type apparatus. The resulting oil was dried by sodium sulphate anhydrous and stored in the refrigerator till be utilized. To identify the main constituents and to determine their relative percentages, Gas chromatographymass spectrometry (GC-MS) device stands at Medicinal and Aromatic Plants Research Department, National Research Centre was used to analyse the essential oil following the conditions mentioned by Omer et al. (2022).

The antioxidant action of the essential oil was determined using a series of diluted essential oil in methanol with varying concentrations (5, 10, 15, 20 and 25 μ L/mL). The method of Tekao et al. (1994) was used to evaluate the essential oil's ability to scavenge DPPH free radicals with some modifications of Kumarasamy et al. (2007).

Larval dipping test

The anti-larval efficacy of *M. longifolia* essential oil on the second and third instar of C. titillator larvae was done during three cuts on the 28th of April, 4th of June and 22nd of July. The larval instars were collected from the slaughtered camels at abattoir, and differentiated as described by Zumpt (1965). The freshly collected larval instars were thoroughly cleaned from mucous utilizing water, and then they were washed several times by PBS pH 7.2. For each treatment, a total of ten second and third larval instars; five for each, were used per replicate. Three replicates were applied. Three concentrations (50, 100, 200 mg/mL) for each cut of *M. longifolia* oils prepared using distilled water with adding of few drops of Tween 80 for emulsification, were used. Ivermectin was purchased as the reference drug from Sigma -Alderich ® developed by Merck & Co., Inc., Kenilworth, NJ, U.S. Ivermectin was used at 0.003 mg/mL. The treated larvae were transported to a mesh cloth place and exposed for sinking for 1 min in a 100mL of oil. Untreated larvae were subjected to diluent, for the same period of time. Then, the treated larvae were reserved in petri-dishes having filter papers (Whatman No. 1) at room temperature 29°C and 80±5% relative humidity. The larval mortality was checked by counting of dead and alive larvae. The larva which exhibited no movement or reflex after its stimulation for several times by smooth ends wooden stick, were considered dead. The mortality was recorded after varies time intervals (2, 4, 6, 8, 10, 12, 18, and 24h). Mortality percentage, LC50 and LC90 were calculated (Table 4 and 5).

Histopathological examination

The histopathological effects of M. longifolia essential oil on C. titillator larvae have been studied according to Bancroft et al. (1996). Three groups of larvae were used (G1; the untreated control exposed to saline, G2: subjected to ivermectin at dose of 0.003mg/mL and G3; exposed to the oil of the 2nd cut (4th of June) at concentration of 200 mg/mL). The larvae were incubated for 6h. The concentration of 200 mg/mL was selected according to the results obtained from the larval dipping test. Post exposures, fixation of larvae was done using 10% neutral buffered formalin. Dehydration of the specimens was performed in graded alcohols, cleaned in xylol and put in paraffin blocks then cut into about 5µm thicknesses finally; they stained with haematoxylin and eosin. The pathohistological effects were investigated using a routine light microscope and photographed

through digital camera.

Scanning electron microscopy

Ultra-structure inspection was fulfilled on larval instars of groups (G1, G2 and G3) according to Hilali et al. (2015). Immersion of the larvae was immediately done in 2.5% glutaraldehyde for fixation. Then they were dehydrated utilizing upgraded ethanol degrees series. A CO_2 critical point drier (Autosamdri-815, Germany) was used for the larvae dryness and after that the larvae glued on stubs; covered with 20nm gold in a sputter coater (Spi-Module sputter Coater, UK). The electron microscope (JSM 5200, Electron probe Microanalyzer, Jeol, Japan) in the electron microscope unit at the National Research Centre, Egypt, was utilized to take images.

Statistical analysis

The analysis of the recorded data for herb yield and essential oil production was done as completely randomized design by analysis of variance (ANOVA) using the General Linear Models procedure of CoStat according to Snedecor and Cochran (1967). Least significant difference (LSD) test was recorded at 0.05 probability levels for the comparison of the means of the treatments. The analysis of the impact of risk factors was achieved using Chi square test by factual computer bundle for social science (SPSS) adaptation 15.0 (SPSS Inc., Chicago, IL), and P<0.05. LC50 and LC90 values were also calculated utilizing log-probit software program Ldp Line® model"Ehabsoft" (Bakr 2000). The obtained data of larval dipping test were analyzed for the mean and standard errors (SE) and statistical comparison between the means of varies treatments for the three cuts (28^{th} of) April, 4th of June and 22nd of July) of *Mentha longifolia* oil was proceeded by one way ANOVA with SPSS program version.

RESULTS

Clinical and postmortem findings

Infested camels examined before slaughtering showed various respiratory signs including heavy mucoid almost bloody nasal discharge, sneezing, snoring, shaking head and general weakness. Some expelled larvae from infested camels were found dropped in the ground of abattoir. As shown in Fig. 1a, the nasopharyngeal region of infested camels was congested where the nasal passages were plugged with dark colored mucous containing. The mucosa was edematous with hemorrhagic patches and several scattered black nodules were also noted. Some larvae were embedded firmly in the mucosa by their sharp black mouth hooks and others were loosely attached or even crawling freely within the nasal and paranasal sinuses, as well as the turbinate bones and ethmoid area. The collected larvae were of different instars (Fig. 1b).

Prevalence of nasopharayngeal myiasis

Nasopharyngeal myiasis was detected among 58% (174) camels out of three hundred ones, along the period extended from February 2024 to January 2025. Monthly detection of C. *titillator* larvae revealed significant high prevalence of infestation during February 88% (22/25); P<0.036 and the lowest one was during June 2024 whereas

the infestation rate reached 24% (6/25) as shown in Table 1. It was remarkable that winter season was of the highest prevalence, whereas 81.3% (61/75) followed by Autumn 66.7% (50/75), Spring, 42.7% (32/75), and Summer 34.7% (26/75) (χ value18.479; P<0.001) as shown in Fig. 2. Age of animals is considered as a risk factor for infestation. The prevalence of nasal myiasis in the adult camels of age more than three years old was prominent 70.8% (124/ 175); (P<0.004) compared with the young ones less than three years 40% (50/125). Sex of animals was not a risk factor for the infection P<0.926. The prevalence during cold season was highly significant P<0.001 where it reached 74% (111/150) Table 2.

Herb yield and essential oil production

The data in Table 3 revealed that the greatest fresh

and dry weights of herb (g plant⁻¹ and ton hectar⁻¹) of *Mentha longifolia* were obtained in the 2nd cut on the 4th of June and no further increases were recorded in the 3rd cut on the 22nd of July, while the highest values of essential oil percentage (1.43%) and yields (1.96mL plant⁻¹ and 87.0L hectar⁻¹) were obtained at the 3rd cut on the 22nd of July.

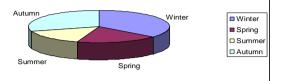

Fig. 2: Seasonal prevalence of nasopharyngeal myiasis among infested camels.

Essential oil constituents

The identified components of *M.* longifolia essential oil are shown in Table 4. The relative percentages of the main constituents showed variation in all three cuts date and oxygenated monoterpenes (86.55, 92.91 and 90.79 % on 28th of April, 4th of June and 22nd of July, respectively) were dominated. The major constituents were pulegone (63.79, 62.41, and 55.25%) followed by eucalyptol (8.88, 14.68 and 18.26%), then I-menthone (6.03, 8.32 and 9.83%) in the 1st, 2nd and 3rd cuts respectively. The highest percentage of pulegone (63.79%) was obtained from the 1st cut on the 28th of April followed by 62. 41% in the 2nd cut on the 22nd of July. In contrast the 3rd cut on the 22nd of July produced the highest percentage of eucalyptol (18.26%) and I-menthone (9.83%).

Antioxidant activity of the essential oil

Data in Table 5 show the effect of cuts on the antioxidant activity of the essential oil of *M. longifolia* plants. It is clear that the cuts have an inversely significant effect on the antioxidant activity which recorded the highest values in the 1st cut (28th of April) and the lowest values in the 3rd cut (22nd of July). There is a significant difference between the first and third cuts in all concentrations used of the essential oil, as well as between the second and third cuts when using 15, 20, and 25μ L/mL concentrations. While the first cut is significantly different from the second cut when using only 20 and 25μ L/mL concentrations.

The highest antioxidant activity (79.4%) resulted by using 25μ L/mL oil of the first cut, followed by 71.8 and 59.3% of the second and third cuts, respectively at the same concentration. In another word, the highest IC₅₀ (20.98 μ L/mL) is obtained at the third cut, followed by 17.70 μ L/mL at the second cut and then 16.20 μ L/mL for the first cut, which confirms the previous results that the essential oil of the first cut led to the highest antioxidant activity.

Effectiveness of M. longifolia oils on C. titillator larvae

M. longifolia essential oil significantly affected the 2nd and 3rd larval stages across three different cut dates (28th of April, 4th of June and 22nd of July), compared to the control group. Mortality percentages, detailed in Table 6 and 7, varied depending on the concentration of the oil and the cut date. For the second larval stage, complete mortality

*IC₅₀ signifies concentration (μ g/mL) for 50% Inhibition.

(100%) occurred within 2h at concentrations of 200mg/mL from the 1st and 2nd cuts (on 28th of April and 4th of June), while the 3rd cut resulted in 100% mortality after 10h of exposure. At 100mg/mL concentration, 100% mortality among the 2nd larval stage was observed 4h after exposure to oil from the 2nd cut (Table 6). The third larval stage showed 100% mortality after 8h at 200 mg/mL from the 2nd cut (Table 7). Mortality reached 93.3% after 24 hours of exposure to 100 and 200mg/mL oil concentrations from the 1st and 3rd cuts, respectively. In contrast, the reference drug, ivermectin, achieved 100% mortality in the second and third larval stages after 10 and 24h, respectively.

Lethal concentration values (LC50 and LC90) were calculated for both larval stages at 2h and are presented in Table 6 and 7 for each cut. The second larval stage exhibited the highest LC50 and LC90 values at the 3^{rd} cut,

with values of 79.698mg/mL and 254.372mg/mL, respectively. The lowest LC50 and LC90 values were recorded at the 2^{nd} cut, at 1.18mg/mL and 74.987mg/mL. For the third larval stage, the highest LC50 and LC90 values were 294.253mg/mL and 2391.451mg/mL, respectively, at the 1^{st} cut, while the lowest values were 119.174mg/mL and 256.31mg/mL at the 2^{nd} cut.

Light microscopic observations

The cuticle of the third instar of *C. tittilator* of nontreated control (group 1) is composed of an epicuticle, and a procuticle. The procuticle is consist of exocuticle, endocuticle, and inner epidermal cells (Fig. 3a and Fig. 3b). The cuticle of the third instar of *C. tittilator* epicuticle layer treated with ivermectin at dose of 0.003mg/mL (group 2) showed wrinkling and corrugation (Fig. 3c and Fig. 3d).

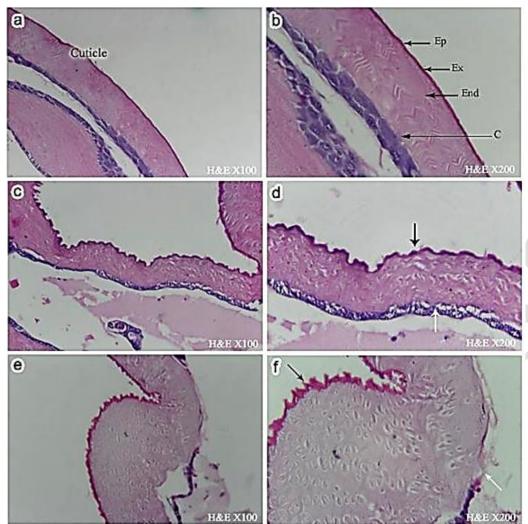

Fig. 3: Light microscopy of the cuticle cross section of the third instar larvae. a, b Untreated control larvae. c. d Following 6h post treatment with 0.003mg/mL ivermectin. e, f Following 6h post treatment with 200mg/mL M. longifolia oil. Note distortion of inner cellular layer of epidermal cells. Ep: epicuticle, Ex: exocuticle, End: endocuticle, Epid: epidermal cell.

The effects of a 200mg/mL concentration of *M. longifolia* oil from the 2^{nd} cut on cuticle morphology (group 3) were examined (Fig. 3e and Fig. 3f) where severe distortion and wrinkling of epicuticle layer were observed. Swelling of the cuticle led to moderate degeneration and atrophy of the fibrils in both the exocuticle and endocuticle was recorded. Furthermore, the inner epidermal cells showed substantial damage (Fig. 3e and Fig. 3f).

The SEM findings

Untreated control C. titillator 3rd instars (group1) appeared to have tiny antenna lobes and an unarmed pseudocephalon with an antenno-maxillary sensory complex consisting of the antenna and maxillary palp, as well as a set of center small coeloconic sensilla and a few outlying sensilla (Fig. 4a). The buccal funnel is already well-structured with powerful mouth hooks (maxillae). The maxillae are highly pointed and ventrally curved, with wrinkle areas and dorsolateral grooves. There are no mandibles (Fig. 4a). A band of tiny spines with irregular rows can be seen ventrally. There are numerous curricular semi-grooves in the abdominal segments, many of which include pits and deep pores (Fig. 4d). The abdominal respiratory spiracles were located at the posterior end of the larval body, contained inside a cuticle ring and connecting to the dorsal and ventral lips (Fig. 4g). The spiracles plate showed signs of significant sclerotization and was packed with many respiratory units that were dispersed throughout the spiracles plates. Every breathing unit featured a slit encircled by rima.

After 6h, third instar larvae of both the reference drug (group 2) (Fig. 4c, Fig. 4f and Fig. 4i) and 200mg/mL of *M. longifolia* oil second cut (group 3) (Fig. 4b, Fig. 4e and Fig. 4h) exhibited unusual features. The majority of investigated specimens showed significant integument edema. The front cuticle surface of group 3 appeared to be more sloughed and corroded than group 2 ivermectin treated, while inter-segmental spins swelled for both groups. Also, *M. longifolia* oil caused significant internal structural damage and shrinking at posterior spiracles more obviously than ivermectin treated one.

DISCUSSION

Prevalence of nasopharayngeal myiasis

Infestation by *C. titillator* is a widely spread among camels and it is associated with severe financial losses (Abu El Ezz et al. 2018). Periodic surveillance of nasopharyngeal myiasis is a need for applying efficient management and control measures. Several studies have reported varying prevalence of nasopharyngeal myiasis, with 67.6% and 52% in Saudi Arabia (Hussein et al. 1983; Fatani and Hilali 1994), 25% in Egypt (Morsy et al. 1998), 41% in Saudi Arabia (Alahmed 2002), 41.67% in Egypt (Khater et al. 2013), 46% in Jordan (Al-Ani and Amr 2016), 40.07% in Iraq (Al-Jindeel et al. 2018) and 54.2% in China (Yao et al. 2022).

Int J Vet Sci, 2025, x(x): xxx.

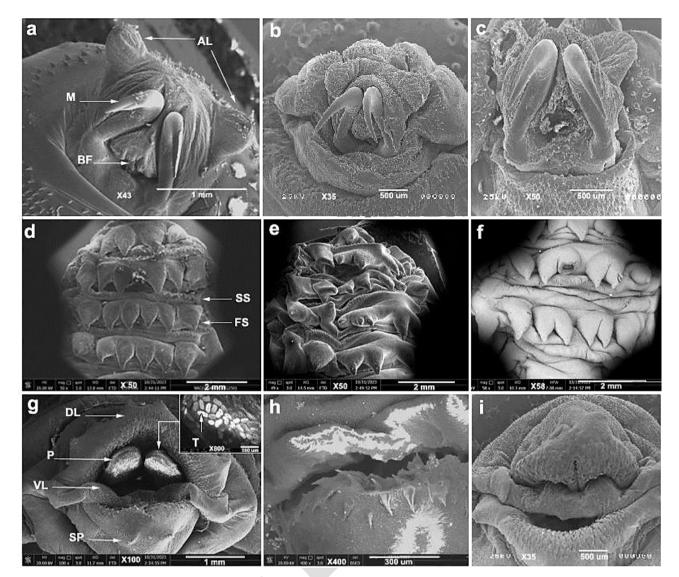

Fig. 4 (a-i): Scanning electron micro-graphs of the third instar *C. tittilator* (L.). a) Normal anterior end and buccal funnel. b) After being exposed for 6 h to 200mg/mL of *M. longifolia* 2^{nd} cut, the anterior end showed severe corrosion. c) After 6h of ivermectin treatment, the anterior end showed sever damage, d) Normal appearance of integument and spines. e, f) The mid region of the larvae treated with *M. longifolia* 2^{nd} cut and ivermectin, respectively, displayed swelling of the intersegmental spine and integument, g) Typical kidney-shaped posterior spiracles with spiracle units. h,i) The treated larvae with *M. longifolia* 2^{nd} cut and ivermectin, respectively, exhibited severe corrosion swelling of the spines in the posterior region, distortion of posterior spiracles, sunken respiratory units, and lost linear shape of respiratory slits. M: maxillae; BF: buccal funnel; AL: antennary lobe; SS: intersegmental spine; FS: fleshy spine; DL: dorsal lip; P: spiracle plate; VL: ventral lip; SP: sensory papillae; T: respiratory slit.

These variations in prevalence across various nations could be due to multiple factors such as environmental conditions, camel populations, and rearing facilities in each region. This study revealed the highest prevalence of infestation in February (88%), with the lowest prevalence observed in June (24%). Notably, the winter season showed the highest overall prevalence at 81.3% (P<0.001). In contrast, the lowest prevalence was observed during the summer season, with a rate of 34.7%. Additionally, the prevalence during the cold season (74%) was significantly higher than in the warm season (38%).

These findings aligned with those obtained by Oryan et al. (2008) in Iran, who observed a higher prevalence of nasal myiasis in colder months, reaching 69.8%, compared to 36.2% in warmer months. Similarly, Jalali et al. (2016) observed a higher prevalence in cold seasons (62.5%) compared to hot seasons (32%) in Iraq. Furthermore, Yao

et al. (2022) in China found that the infestation rate was higher in the cold season (64.2%) than in the warm season (48.4%). Morsy et al. (1998) also reported that autumn had the highest prevalence of nasal myiasis among camels in Egypt. The higher prevalence of nasopharyngeal myiasis in camels during the cold season might be attributed to the increased survival and development of larvae in lower temperatures and/or the management and feeding systems of the animals.

The results of the current study revealed a higher infestation rate in camels older than three years (70.8%) compared to those younger than three years (40%). This finding was consistent with previous studies by Fatani and Hilali (1994), El Bassiony et al. (2005), Sanchez (2010), and Yao et al. (2022). According to Bekele and Molla (2001) and Shakerian et al. (2011), adult camels with mature, heavier bodies were more tolerant to infestation, allowing flies to deposit eggs around their nostrils, while younger camels tended to actively avoid egg deposition near their nostrils. The present study also found that the sex of the animals was not a significant risk factor for infestation (P>0.05). This result aligned with findings by Shakerian et al. (2011) and Yao et al. (2022), who found that there was no significant difference in nasal myiasis infestation between male and female camels.

Up till now the traditional approach of nasopharyngeal myiasis treatment is using chemotherapeutics, despite their inefficacy. Production of eco-friendly alternatives is a need to overcome the medical, economical and environmental concerns of emerging drug resistance.

Herb yield and essential oil production

Harvest cut may have an impact on herb yield due to temperature, sunshine accumulation, and available day length (Figueiredo et al. 2008). These results are agreed with Omer et al. (2022) who showed that when harvesting dates were postponed until July 12 for pennyroyal and July 26 for apple mint, the fresh and dry weight of the herb increased. Aziz et al. (2019) stated that the highest herb yield of *Achillea millefolium*, and the best essential oil content and composition of it can be obtained according to the harvest time and climatic conditions.

Essential oil constituents

The cut dates had a significant impact on the main components of M. longifolia essential oil, and displayed significant variances in the percentage and the identified constituents. These results agreed with Shahbazi et al. (2021) who revealed that pulegone (47.20%), 1,8 cineole (22.72%) and menthone (13.44%) are the main components of the essential oil of M. longifolia. Also, pulegone, E-Menthone, Z-menthone, eucalyptol were the major constituents of M. longifolia essential oil (Abdel-Gwad et al. 2022). Fouad et al. (2023) stated that the 2nd cut on the 12th of June was found to be suitable for producing the greatest percentage of pulegone in *M. pulegium* and *M.* Longifolia, linalyl acetate in M. suaveolens, as well as increasing the value carvone in *M. spicata*. However, the biosynthesis of Linalool and eucalyptol in *M. suaveolens* as well as D-limonene in M. spicata and M. viridis increased when the third cut was delayed until August 1. Omer et al. (2022) showed that pulegone was found to be the major constituent of pennyroyal oil and the highest relative concentration (94.89 %) was obtained at the 2nd harvest date on 17th of May. The later harvest date in July 26th produced the highest relative concentration of p-menthan-3-one, cis (48.14 %) and the lowest concentration of pulegone (46.91%). Increasing plant age increased the biosynthesis of cis-p-menthan-3-one and decreased pulegone amount. Also, the transformation rate of cis-pmenthan-3-one to pulegone is influenced by the environmental factors and conditions.

Antioxidant activity of the essential oil

The highest antioxidant activity of the essential oil of the first cut could be attributed to its highest content (63.79%) of the main component (Pulegone) compared to the other two cuts. Pulegone has very strong antioxidant activity as mentioned by Ruberto and Baratta (2000), Demirci et al. (2011) and Silva et al. (2012). Moreover, the first cut has the highest content of monoterpenes hydrocarbons (7.25%) which may be considered as active antioxidants (Ruberto and Baratta 2000).

Effectiveness of M. longifolia oil on C. titillator larvae

The current in vitro treatment of C. titillator showed that the mortality rates of the larvae varied depending on the concentrations of *M. longifolia* oils and the dates of the cuts. The second larval stage exhibited complete mortality (100%) within 2h when exposed to 200mg/mL concentrations from the 1st and 2nd cuts (28th of April and 4th of June), and within 10h for the 3rd cut (22nd of July). At 100mg/mL, the second larval stage showed 100% mortality 4h after exposure to oil from the 2^{nd} cut. This high efficacy indicates that *M. longifolia* oil is highly effective at various concentrations and exposure times, particularly for the second larval stage. Similarly, the third larval stage exhibited 100% mortality 8h post-exposure to 200mg/mL oil from the 2nd cut. Although the mortality rate reached 93.3% after 24h of exposure to 100 and 200mg/mL concentrations from the 1st and 3rd cuts, respectively, the third larval stage was slightly less susceptible than the second stage under the same conditions. The differential effectiveness observed in M. longifolia oil based on cut dates. Garcia et al. (2018) suggested that the chemical composition of essential oils plays a critical role in their effectiveness. Similar findings have been reported for other essential oils, such as Eucalyptus globulus, where both composition and efficacy varied depending on the harvest season and extraction method (Santos et al. 2019).

These variations highlighted the importance of optimizing harvest times to enhance the larvicidal potential of essential oils. Notably, the study compared these results with the effectiveness of the reference drug, ivermectin, which caused 100% mortality in both the 2^{nd} and 3^{rd} larval stages at 10 and 24h post-treatment, respectively. This comparison emphasized the potential of *M. longifolia* oil as a promising alternative to traditional chemical treatments.

Likewise, Khater et al. (2013) mentioned the anti parasitic action of lavender (50%) on *C. titillator* larvae. Moreover Abu El Ezz et al. (2018) recorded the priority of the effect of camphor oil than ginger and cinnamon oils on the third larvae of *C. tittilator*.

Moreover, the LC50 and LC90 values, further illustrated the effectiveness of the essential oils. The 2^{nd} larval stage exhibited the lowest values of LC50 and LC90 with 1.18 and 74.987mg/mL, while, for the 3^{rd} larval stage were 119.174 and 256.31mg/mL at the 2^{nd} cut. These findings suggest that the effectiveness of *M. longifolia* oil can vary significantly depending on the cut date and concentration, with the 2^{nd} cut on being particularly potent. The differential effectiveness observed between the different larval stages and cut dates can be attributed to the variations in the chemical composition of the essential oils extracted at different times (Garcia et al. 2018). The potent larvicidal activity, especially at the 2^{nd} cut on 4^{th} of June, highlights the importance of optimizing harvest times to maximize the efficacy of essential oils as bio-insecticides.

Light and electron scanning microscopic observations

The cuticular structure of the third instar of C. *tittilator* (L.) is essential for its protection and interaction with the environment. Significant damage to the inner epidermal cells was also observed. These cells are crucial for the

synthesis and maintenance of the cuticle (Gillott 2005). Damage to the epidermal cells can impair the production of new cuticular material and the repair of existing structures, leading to long-term detrimental effects on the insect's health and development. These findings align with other research indicating the potential of botanical extracts to interfere with insect cuticle formation and function. For instance, essential oils from plants like Azadirachta indica (neem) have been shown to disrupt cuticle synthesis and cause morphological abnormalities on mosquito vector Culex pipiens (L.) (Ahmed et al. 2023). The observations from the SEM analysis of C. titillator (L.) third instars after 6h of treatment with both the reference drug and 200mg/mL of *M. longifolia* oil of the second cut reveal several noteworthy changes in larval morphology. Recent studies have similarly observed integumentary disruptions in insect larvae subjected to various treatments. Jiménez-Durán et al. (2021) reported that exposure to certain phytochemicals led to pronounced edema and structural degradation of the cuticle in Spodoptera litura. These findings are consistent with our observations of integument edema and surface corrosion. The swelling of intersegmental spines observed in our study aligns with the findings of Stadler and Buteler (2009) and Abu El Ezz et al. (2018) who detected severe cell membrane disruption and darkening following exposure to essential oils. Najar-Rodríguez et al. (2007) showed the capability of essential oils to sneak the cell membranes and accumulate within the cytoplasm prompting dehydration of the cell and condensation of DNA inside the nucleus. The insecticidal activity of *M. longifolia* oil was primarily attributed to oxygenated monoterpenes, Pulegone, a monoterpene, is an active compound in M. longifolia essential oil that can penetrate bacterial cell walls, leading to protein denaturation and disintegration of the cell membrane. This causes cytoplasmic leakage, cell lysis, and ultimately cell death (Oussalah et al. 2007). Pulegone has been shown to effectively combat S. aureus, S. typhimurium, and E. coli (Farhanghi et al. 2022). The lipophilic nature of essential oils helps increase membrane permeability or cause membrane destruction due to the activity of enzymes like protein kinase in the cell membrane (Vogt 2010). This suggested that M. longifolia essential oil could serve as a viable alternative to traditional chemical control strategies. Additionally, Khani and Asghari (2012) found that the essential oil demonstrated anti-insect properties against Tribolium castaneum, a pest of stored products, and showed inhibitory effects on insect growth at the larval and pupal stages, along with insect-repellent activity (Pascual-Villalobos and Robledo 1998).

Thus, these findings suggested that mint species' essential oils can serve as natural larvicidal agents, offering a safer and more efficient alternative to chemical insecticides for humans, livestock and the environment.

Conclusion

The study drew attention to the high prevalence of nasopharyngeal myiasis in camels in Giza Governorate, Egypt. The risk factors associated with high infestation included the cooler seasons particularly winter and autumn, and being older camels. The cuts dates affect the rate of accumulation of the major constituents of *M. longifolia* essential oil and revealed great variations in the

percentage and the identified components. The highest relative concentration of pulegone (63.79%) was obtained from the 1st cut on the 28th of April followed by 62. 41% in the 2nd cut on the 4th of June. This study also highlighted the potent larvicidal effects of *M. longifolia* oil, based on harvest timing for both 2nd and 3th larval instars of *C. titillator* particularly at concentration 200mg/mL oil from the 2nd cut compared to control untreated and ivermectin treated larvae. It could be concluded that *M. longifolia* essential oil could serve as a promising natural insecticides, offering an environmentally friendly alternative to traditional treatments or complementary with the chemotherapeutics.
